Image-based transcranial sonography is a promising method for functional imaging of the brain. However, transcranial sonography is limited by its resolution, which is comparable to that of conventional diagnostic magnetic resonance imaging. Furthermore, the signal-to-noise ratio is extremely low. In this study, we performed a quantitative analysis of the reproducibility of transcranial sonography using a hidden Markov model (HMM), which is a time-series analysis technique. We applied HMM to a single-beam echo-planar sequence to measure the reproducibility of image sequences. We measured 10 normal volunteers (20 times) and compared the imaging sequences in two different planes, and analyzed the effect of decreasing image noise on the quality of the imaging. By applying HMM to a single-beam echo-planar sequence, we measured the reproducibility of imaging sequences. We compared the quality of single-beam and multi-section image sequences (20 slices in each plane) and analyzed the effect of decreasing image noise on the quality of the imaging. Transcranial sonography with single-beam echo-planar sequences showed a higher reproducibility than with multi-section image sequences. Decreasing image noise improved the contrast of single-beam sequences. The reproducibility 2d92ce491b
